Reyes_Lab1.py x
1 card_number = "4532-8812-9001-4321"
2
3 parts = card_number.split("-")
4
5 for i in range(len(parts) - 1):
6     parts[i] = "*****"
7
8 masked_card = "-".join(parts)
9
10 print("Original Card Number:", card_number)
11 print("Masked Card Number:", masked_card)
12
13

Shell x
>>> %Run Reyes_Lab1.py
Original Card Number: 4532-8812-9001-4321
Masked Card Number: *****-4321
>>>
```

This image displays the implementation of the "Last-Four" masking rule designed to protect Personally Identifiable Information (PII) while keeping enough data for customer verification. The Python script isolates the segments of a credit card number by using the `split("-")` method to create a list of strings. It then iterates through the list to replace the initial segments with asterisks, leaving only the final part untouched. Finally, the script uses the `"-".join()` method to re-assemble the parts into a single string that preserves the original hyphen formatting.

12
13 phone_number = "123-456-7890"
14 phone_parts = phone_number.split("-")
15
16 for i in range(len(phone_parts) - 1):
17     phone_parts[i] = "****"
18
19 masked_phone = "-".join(phone_parts)
20
21 print("\nOriginal Phone Number:", phone_number)
22 print("Masked Phone Number:", masked_phone)

Shell x
>>> %Run Reyes_Lab1.py

Original Card Number: 4532-8812-9001-4321
Masked Card Number: *****-4321

Original Phone Number: 123-456-7890
Masked Phone Number: ****-7890

>>>
```

This image shows the results of the validation test where the masking utility is applied to a phone number to ensure the code works regardless of the input type. By testing the script with the string "123-456-7890," the output demonstrates that the logic correctly hides the first two segments and reveals only the last four digits. This successful test confirms that the function is well-written and automatically adapts to different PII formats as required by the lab constraints.
